solid = first in family, ring/dashed = second, striped/dotted = third

The public data ends on 23 May 2026, so these are the calls for the week after 17 May 2026. Re-run with newer data to update them. Each expert gives the chance that Bitcoin is higher in 7 days. At 55% or more it goes LONG; at 45% or less, SHORT; in between, FLAT. Phantom Flow gives a confluence score instead (−3 to +3, shown on the same scale); it acts only when its trend shift and oscillator agree and structure does not contradict. The market expert is different: it is not a model but the price of prediction-market contracts, and it abstains on any week with no liquid market. The panel chair acts when at least 3 experts agree and they outnumber those on the other side.

Does it depend on the settings?

Phantom Flow alone	pivot 3d	pivot 5d	pivot 10d
ATR × 2	0.62	0.48	0.88
ATR × 3	0.55	0.58	0.98
ATR × 4	0.45	0.41	0.90

Buy & hold: 0.93.

Sharpe ratio over the whole test for other ATR multipliers and pivot lengths: Phantom Flow on its own, and the six-expert panel chair using that version. The outlined cell is the setting used, fixed before the backtest; the others are only a check.

Panel chair with it	pivot 3d	pivot 5d	pivot 10d
ATR × 2	1.05	0.99	1.09
ATR × 3	1.10	1.05	1.14
ATR × 4	1.10	1.05	1.12

Chair without Phantom Flow: 0.93.

Chart pattern and on-chain valuation

Chart JEPA — what the model actually sees

The last 52 weekly closes, drawn as a 24×52 picture and scaled to its own high and low, so only the **shape** survives. The model embeds the strips left of the line and predicts the embedding of the strips right of it — never the pixels.

One reads the chart as a picture; the other ignores the chart entirely and asks what Bitcoin is worth. They were added together, so their effect is measured against the seven-expert chair.

Fundamentals — four on-chain measures

Each is scored against its own previous four years, then signed so **right of centre is bullish**. The seat votes only when their average passes ±0.50.

Average **-0.32**, so the seat is **FLAT**. Bars are standard deviations from each measure's own four-year norm; left of centre is bearish.

13 strips of 4 weeks, 32-dimensional embeddings. **Embedding spread 1.06** — a JEPA fails by mapping every chart to the same point, which would show as a spread near zero, so it is measured on every run and reported whatever it says.

The two newest seats: quantum and regime

Quantum NN — six qubit measurements

<Z> on each of the six qubits after the circuit runs on this week's features, each in [-1, +1]. A classical linear layer turns these six numbers into P(up). Simulated exactly on 6 qubits / 25 parameters — real quantum mechanics, no claimed quantum advantage.

Feature order written into the six qubits: mom_4w, mom_12w, vol_4w, mvr_v, dd_52w, vix.
Current call: **FLAT**.

One is a real (simulated) quantum circuit reading momentum, valuation and volatility as rotation angles; the other is a hidden Markov model that names which market regime we are in, using only weeks that have already happened. They were added together, so their effect is measured against the nine-expert chair.

HMM Regime — filtered state probabilities

Where the model thinks we are right now, using **only** weeks up to and including this one (forward-filtered, never smoothed — smoothing would look into the future). Each state's own average weekly return and volatility appear below.

Did each new seat actually help?

Every time a seat is added the headline number moves and it is tempting to call that progress. Each row re-draws the history in 8-week blocks 4,000 times, so a gap that is really luck shows up as an interval crossing zero. The pass condition was fixed before any of these were run.

Seat added	Sharpe before	after	difference	95% interval	Weeks changed	Excluding 2020	Verdict
Phantom Flow	0.93	1.05	+0.12	[-0.22, +0.50]	57 of 332	0.53 → 0.55	not proven: the interval includes zero
the market seat	1.05	1.05	+0.00	[+0.00, +0.00]	0 of 332	0.55 → 0.55	not proven: the interval includes zero
chart JEPA + fundamentals	1.05	1.21	+0.16	[-0.11, +0.44]	38 of 332	0.55 → 0.72	not proven: the interval includes zero
quantum NN + regime HMM	1.21	1.07	-0.14	[-0.48, +0.17]	54 of 332	0.72 → 0.52	not proven: the interval includes zero

Read this before believing any jump. Each row is judged on its own: an 8-week block bootstrap puts a 95% interval around the Sharpe difference, and the verdict is fixed in advance — entirely above zero improved the committee, straddling zero is **not proven** whatever the headline number says, entirely below zero made it worse. The newest step (quantum NN + regime HMM) moved the committee's Sharpe from 1.21 to 1.07: not proven: the interval includes zero. It does not survive dropping 2020, so treat it with more suspicion. The step before it (chart JEPA + fundamentals) moved Sharpe from 1.05 to 1.21: not proven: the interval includes zero. The mechanism there is worth knowing — the fundamentals seat was bearish for most of the test and turned an undecided FLAT into a SHORT repeatedly; a permanently bearish voice looks good in any sample containing a crash and poor in one without.

The market's own view

The other six experts are models. This one is the crowd: what people actually pay for Bitcoin contracts. It compares the price of a +10% move with an equidistant -10% move, so a risk premium sitting on both legs cancels out.

Not fetched yet. This run has no prediction-market data, so the market expert abstained on all 332 scored weeks and the panel's results above are exactly what they were without it.

The Polymarket and Kalshi APIs are free and public, but were unreachable from the machine that built this page. To fill it in, run:

python code/fetch_markets.py

 then

python code/panel_backtest.py --offline

 and

python code/make_dashboard.py

Expect roughly the last 1-2 years to be covered and nothing before that: liquid Bitcoin prediction markets are recent, so there is no history to backfill.

Who sits on the panel

- **Random Forest** and **Tabular Transformer**: the two model families from the quant research project (projectskf), retrained here to classify next-week direction from 12 market and on-chain inputs.
- **Neuroplastic World Model**: the V5 predictive-latent ensemble (neuroplastic-financial-world-model). Six networks learn to predict the next state of the Bitcoin "world" and next week's return; it trades only when 4 of 6 agree.

Read this before trusting the numbers

- Every model is retrained each January on data before that year, then used unchanged for the year. Nothing sees the future, but this is still one historical path of about 330 weeks.
- 2020–2021 was a strong bull market, so buy and hold is hard to beat on return. Compare drawdowns and Sharpe ratios too.
- The mini LLM memorised the past tape: on new data its surprise (about 4.9 bits a day) was worse than blind guessing (2.8 bits), and its results faded after

- **Jev (System One):** TypeSafe AI's decision model answers "Will Bitcoin be higher in 7 days?" and names the market regime. **In this run it is an offline stand-in, not Jev:** a fixed trend-and-valuation rule.
- **Mini LLM tape reader:** the from-scratch GPT in `tiny-llm2`, trained on daily returns written as letters (a = big fall ... g = big rise). It writes 256 possible next weeks and reports how many end higher.
- **Phantom Flow:** an open re-implementation of the paid TradingView indicator's three published modules on daily closes: an ATR trend shift ($\text{ATR} \times 3$), swing structure (breaks of 5-day swing highs and lows) and an oscillator (distance from the 21-day average in ATRs). Its "combo" call needs shift and oscillator to agree and structure not to disagree. It needs no training, so it is not refitted each year.
- **Chart JEPA:** the technical-analysis seat. A **joint embedding predictive architecture** — LeCun's idea — renders the last 52 weeks as a picture and learns to predict the *embedding* of the next piece of chart rather than its pixels, because pixels are mostly noise. A logistic probe turns that predicted embedding into a probability. The window is scaled to its own high and low, so the model sees shape, never price level.
- **Fundamentals:** the only seat that never looks at price action. It reads four on-chain measures — price against what holders paid (MVRV), miner revenue against normal (Puell), the hash-rate trend, and price against adoption (Metcalf) — each scored against its own previous four years. Fundamentals are slow, so it changes its mind rarely and is expected to be weak week to week.
- **Market consensus:** not a model. Polymarket runs Bitcoin contracts as a ladder of "will it reach \$X" bets, so the prices are a picture of the range the crowd expects. The signal is the gap between what a +10% move costs and what a −10% move costs. It **abstains** whenever no liquid market existed, which is most of 2020–2024, because these markets did not exist then.
- **Panel chair:** LONG or SHORT when at least 3 experts agree and they outnumber the other side. The two dashed grey lines are the earlier chairs — 3 of 5 (no Phantom Flow) and 3 of 6 (no market) — kept to show what each new expert adds.

2021.

- The Jev figures come from the stand-in. Set an API key and re-run to test the real model.
- **Adding Phantom Flow lifted the chair's Sharpe from 0.93 to 1.07, but that may be luck.** The 95% range of the difference is −0.42 to +0.71, and most of the gain came in 2020: excluding it, 0.52 against 0.53. Phantom Flow alone did worse than buy and hold.
- **The market expert has no data in this run and abstained throughout.** Every number above is therefore the six-expert panel. Its own results, and the test of whether the panel beats the traded price, appear once `fetch_markets.py` has been run.
- Phantom Flow here is not the proprietary script, whose formulas are private: it follows the published description with standard formulas, uses closes only (no order blocks or fair value gaps) and cannot repaint, because a swing point only counts once the 5 days after it have closed.
- Research on historical data, not investment advice.

Data: [Coin Metrics community data](#) (CC BY-NC 4.0) to 23 May 2026; CBOE VIX via [datasets/finance-vix](#). Weekly Sunday-to-Sunday decisions, 10 bp cost per unit of turnover, no leverage.
